## **Optimisation in deep learning**

**Goodfellow et al**

# Deep Mysteries of Deep Learning

- Why does it converge at all?
- Why does it work well?
  - non-convex optimisation
  - many local minima
  - generalises to unseen data
- How does regularisation happen?
- Why do high dimensions seem to help?
  - segue into project...

## What is (Supervised) ML<sup>2</sup>?

Given data  $\{x_i, y_i\}_{i=1}^N$  and a model  $g(x_i; w)$ ,  
 $G(x_i)$

Find  $w$  s.t.  $g$  is a good approximator of  $G$ .

Training:  $\hat{w} = \arg \min_w \frac{1}{N} \sum_{i=1}^N \ell(G(x_i), g(x_i, w))$

Testing: What we actually want is

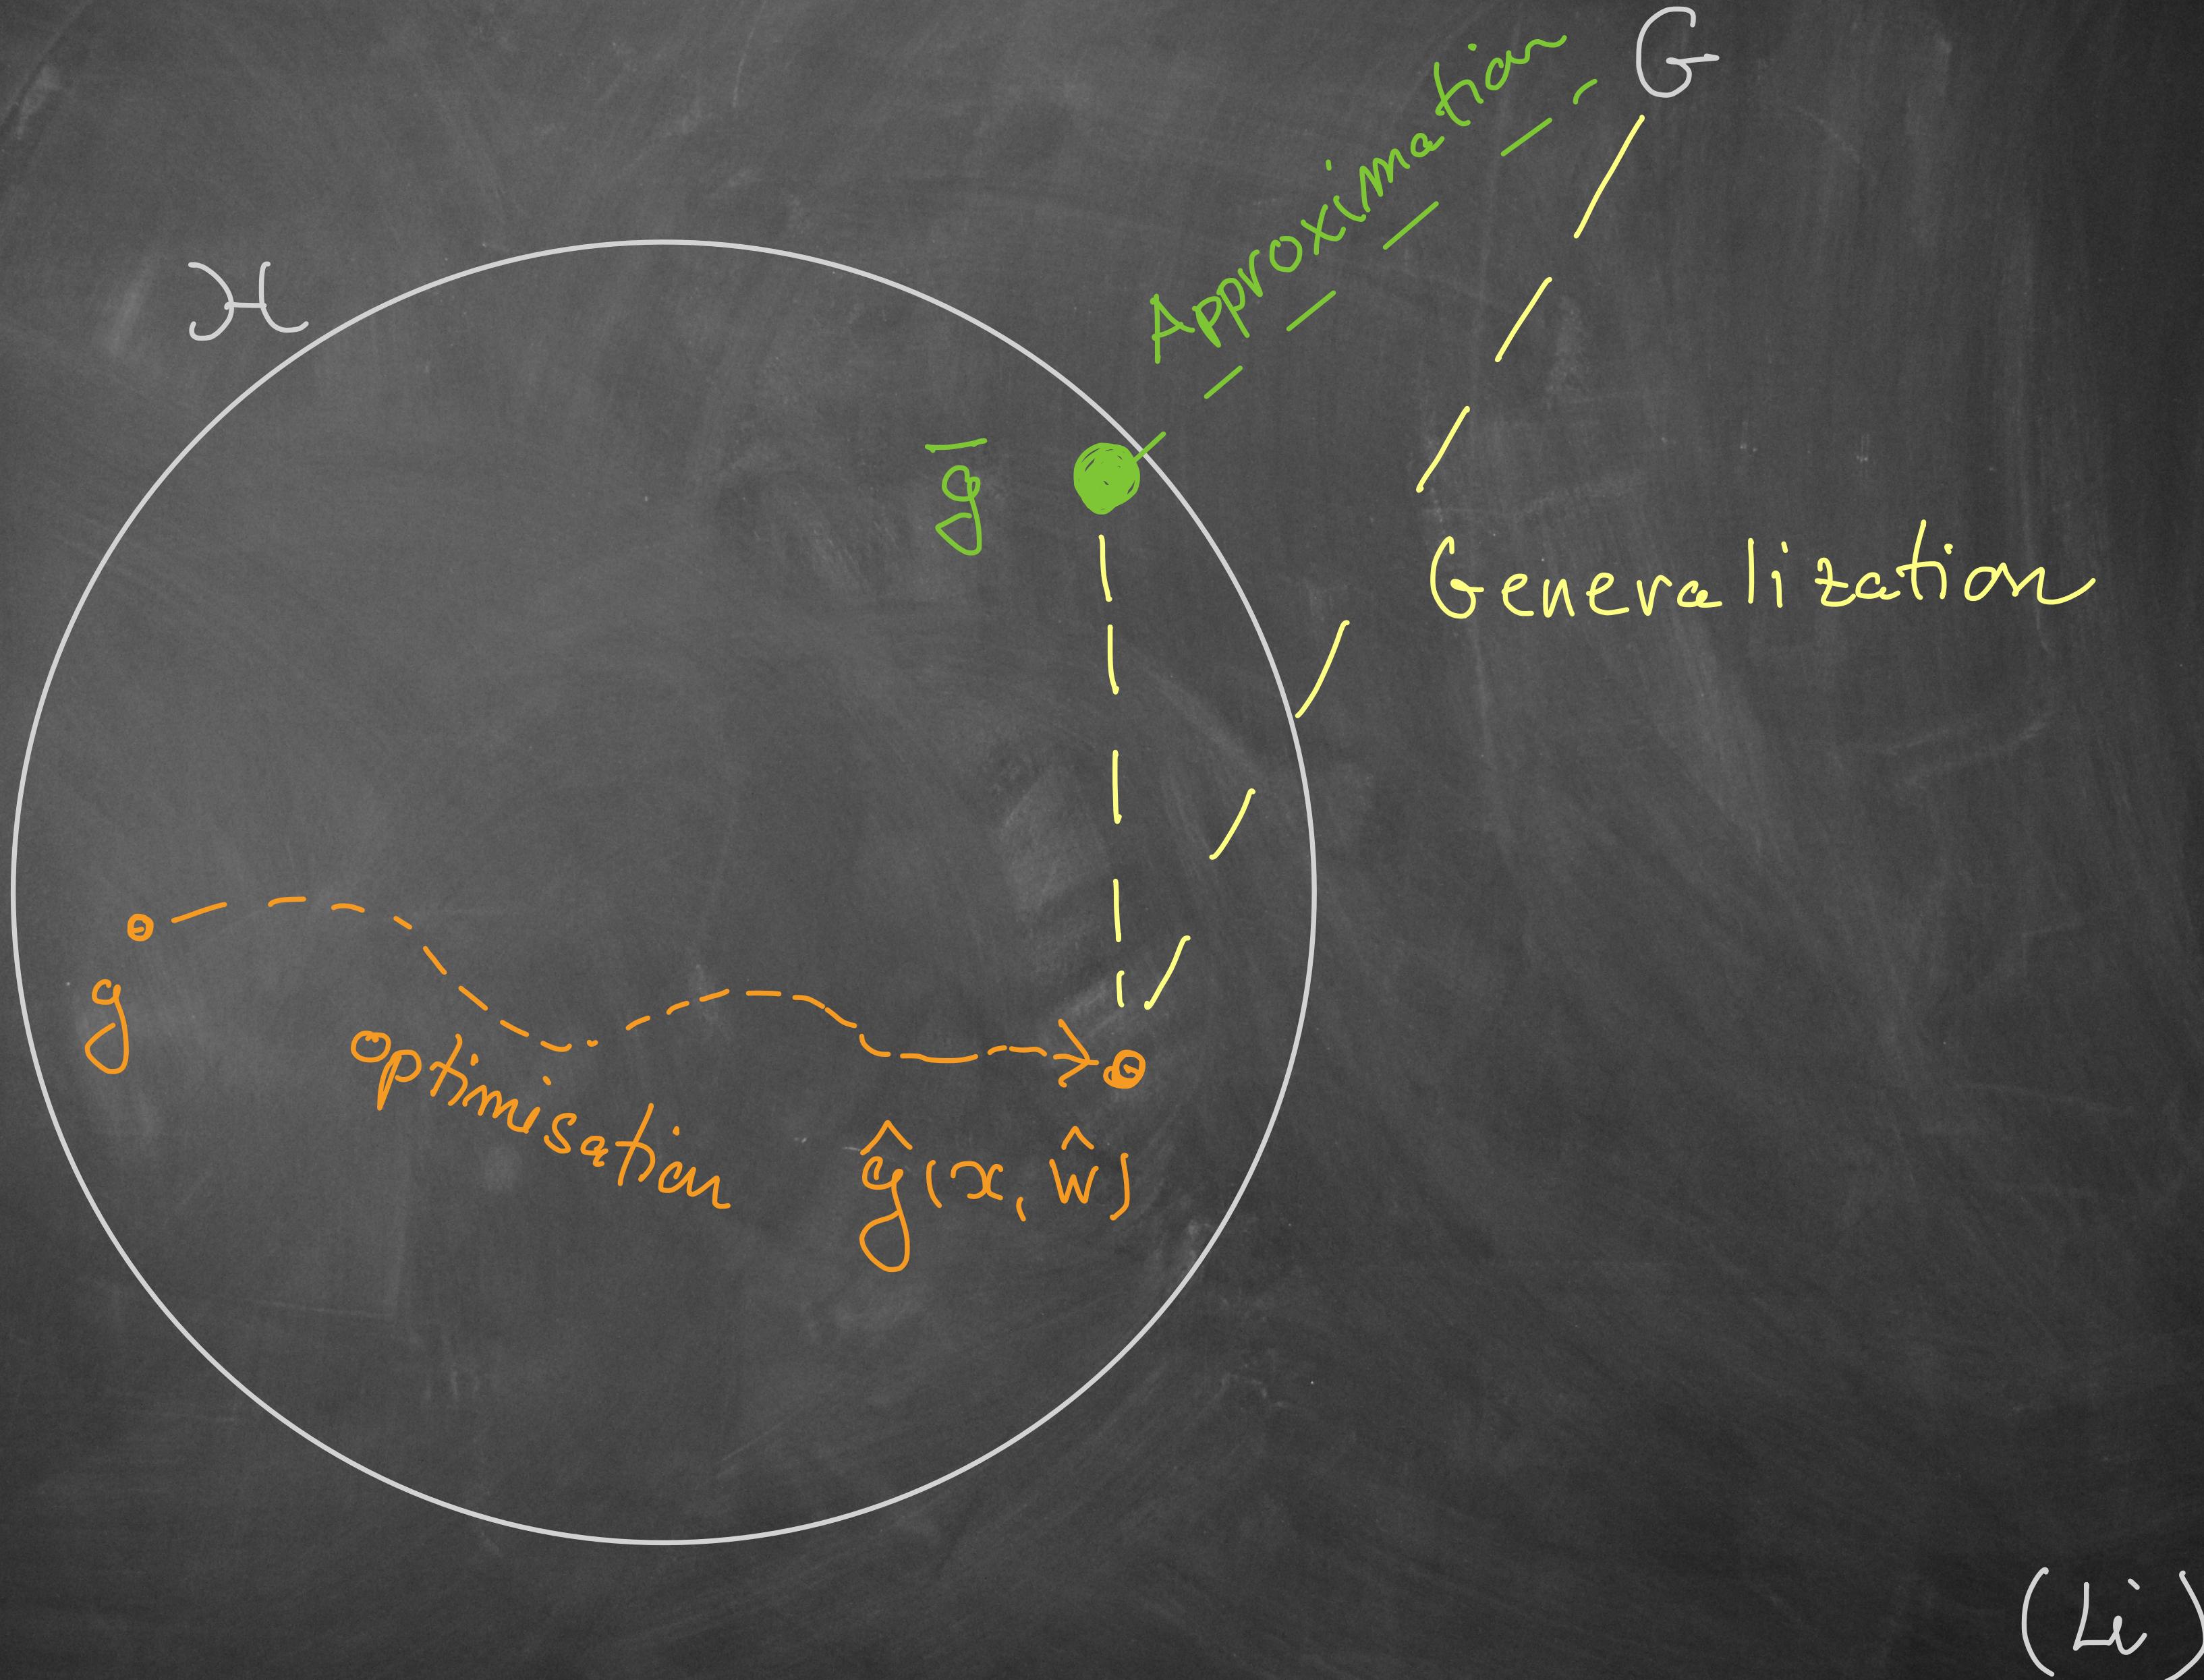

$$\hat{w}^* = \arg \min \mathbb{E}_{x \sim P} \ell(G(x), g(x, w))$$

This poses 3 separate (but interlinked) aspects:

Approximation: choice of model (Hypothesis space)

Optimization: how to find  $\hat{w}$

Generalization: how good is  $\hat{g}(x, \hat{w})$  on unseen  
data

# How to think about ML

## Optimisation

- Why does gradient descent work so well?
- Statistical mechanics
- Why do momentum methods work even better?  
continuous time perspective

## Deep Residual Networks

### Architecture

- Why do some architectures work better than others?  
continuous time perspective

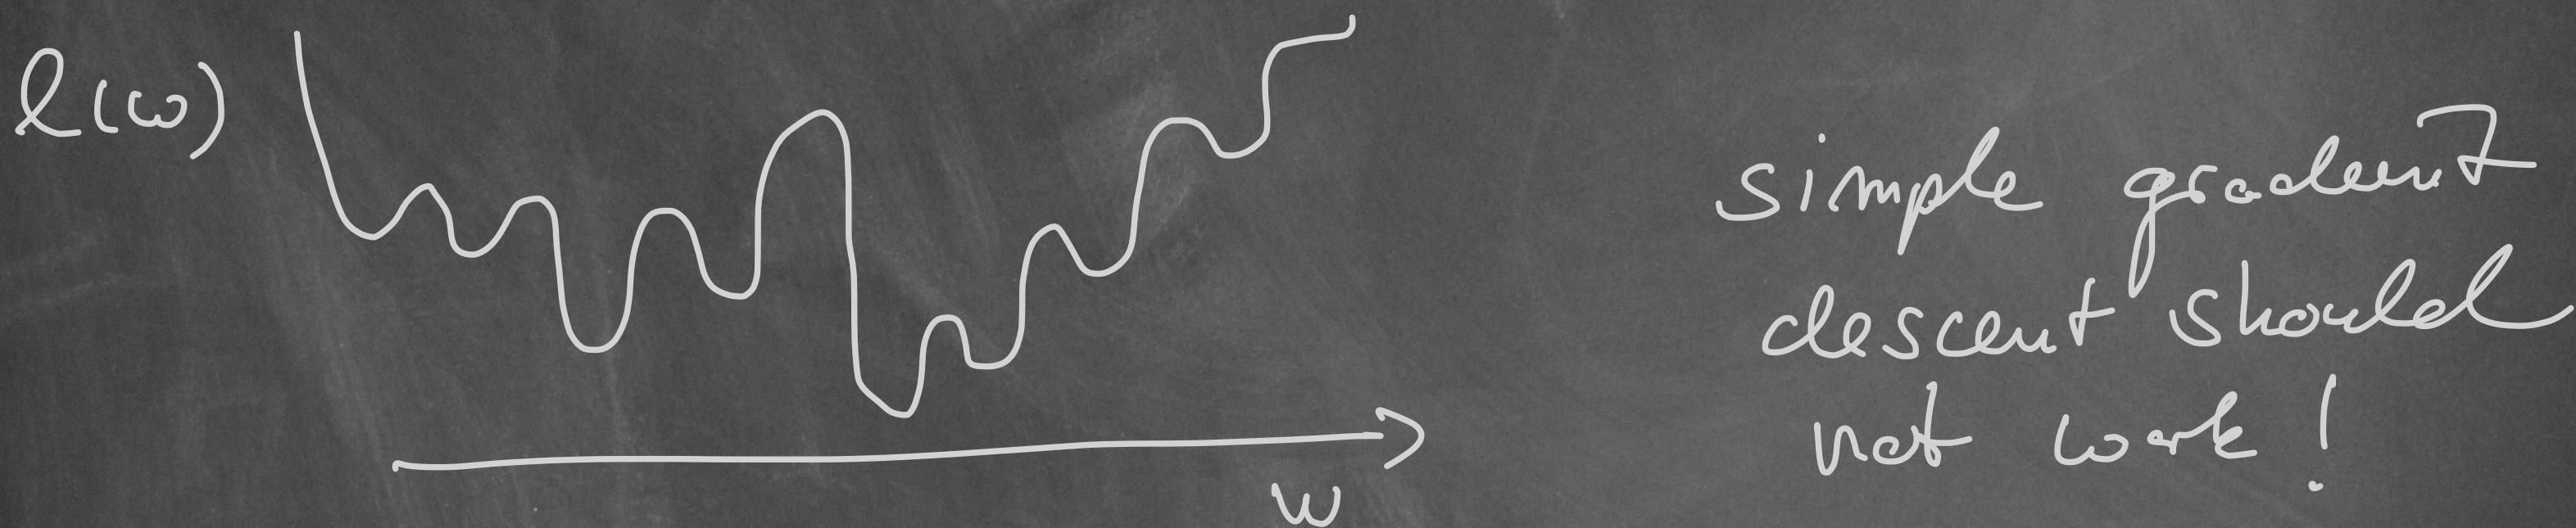

## Approximation Error

- What type of functions can a neural network approximate?  
Function spaces

# The landscape of loss functions

Mean-square error :  $\ell(w) = \sum_{j=1}^N \|y_j - \hat{g}(x_j; w)\|^2$

This is a nonconvex function, so in principle we can have multiple minima (alongside maxima and saddle points)

- Observation:
- \* simple gradient descent works well to train high-dimensional deep neural nets and works less well in shallow networks
  - \* shallow networks can match accuracy of deep networks (similar expressivity)  
(Ba & Carreira 2014)

# High-dimension non-convex cost functions

What type of critical point is most common?

- Global minima?
- Local minima?
- Saddle points?
- Local maxima?
- Global maxima?

(What does the distribution of eigenvalues of a large, random Hessian look like?)

# Gradient Descent and the Structure of Neural Network Cost Functions

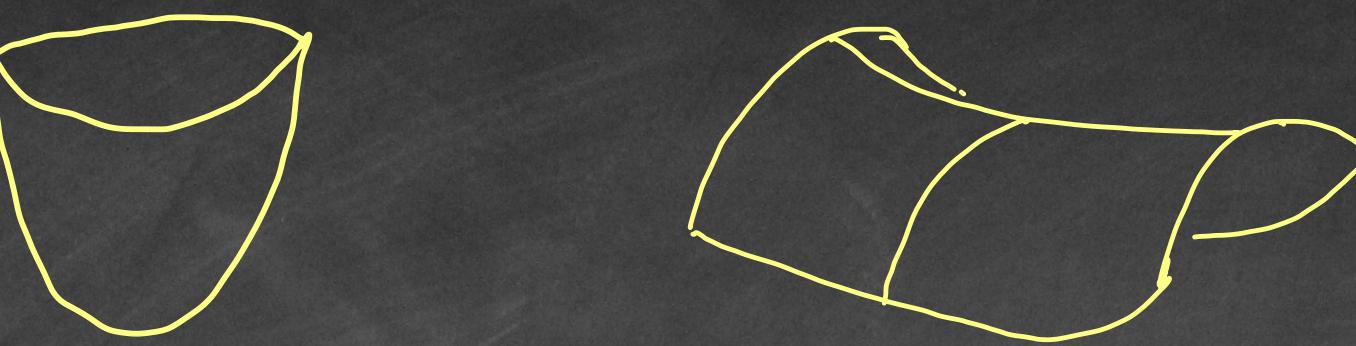

presentation by Ian Goodfellow

adapted for [www.deeplearningbook.org](http://www.deeplearningbook.org)  
from a presentation to the  
CIFAR Deep Learning summer school on August 9, 2015

# Are saddle points or local minima more common?

- Imagine for each eigenvalue, you flip a coin
- If heads, the eigenvalue is positive, if tails, negative
- Need to get all heads to have a minimum
- Higher dimensions -> exponentially less likely to get all heads
- Random matrix theory:
- The coin is weighted; the lower  $J$  is, the more likely to be heads
  - So most local minima have low  $J$ !
  - Most critical points with high  $J$  are saddle points!

Basic intuition:

For a minimum in  $\mathbb{R}^d$  all  $d$  eigenvalues of the Hessian are positive; at a saddle point some are positive, some are negative (ignoring the case of semi-definite Hessians).

Draw the sign of the eigenvalues of the Hessian by coin tossing

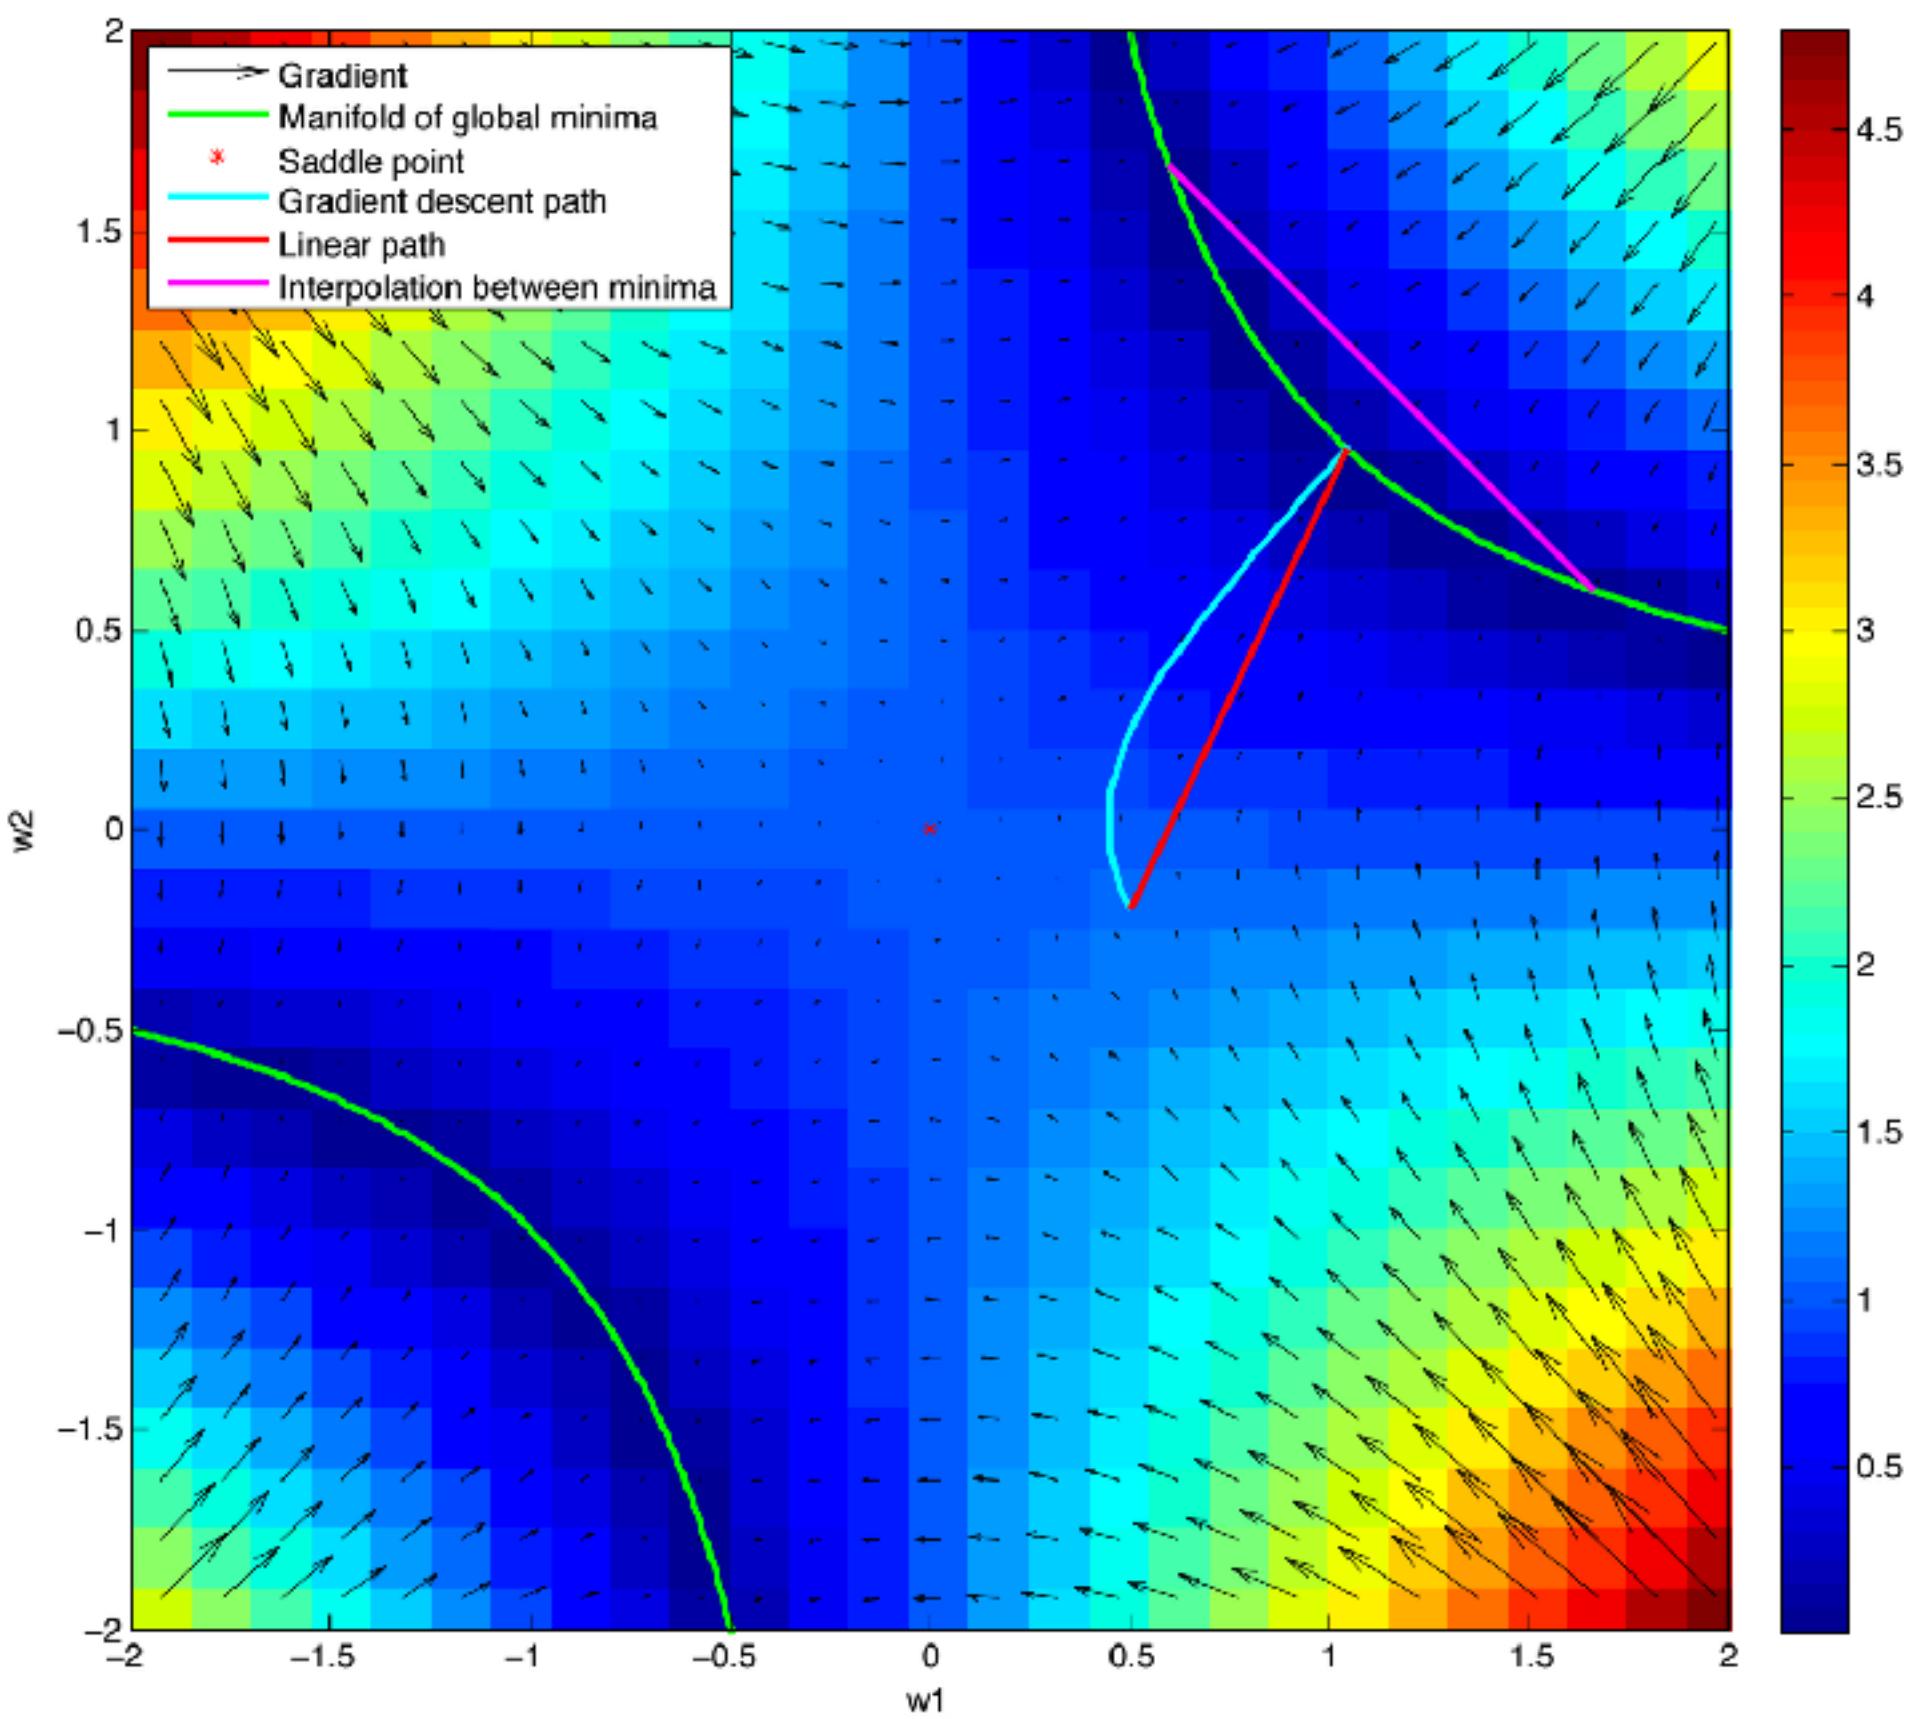

→ Getting a minimum becomes exponentially less likely for increasing dimension  $d$ .

But we need more:

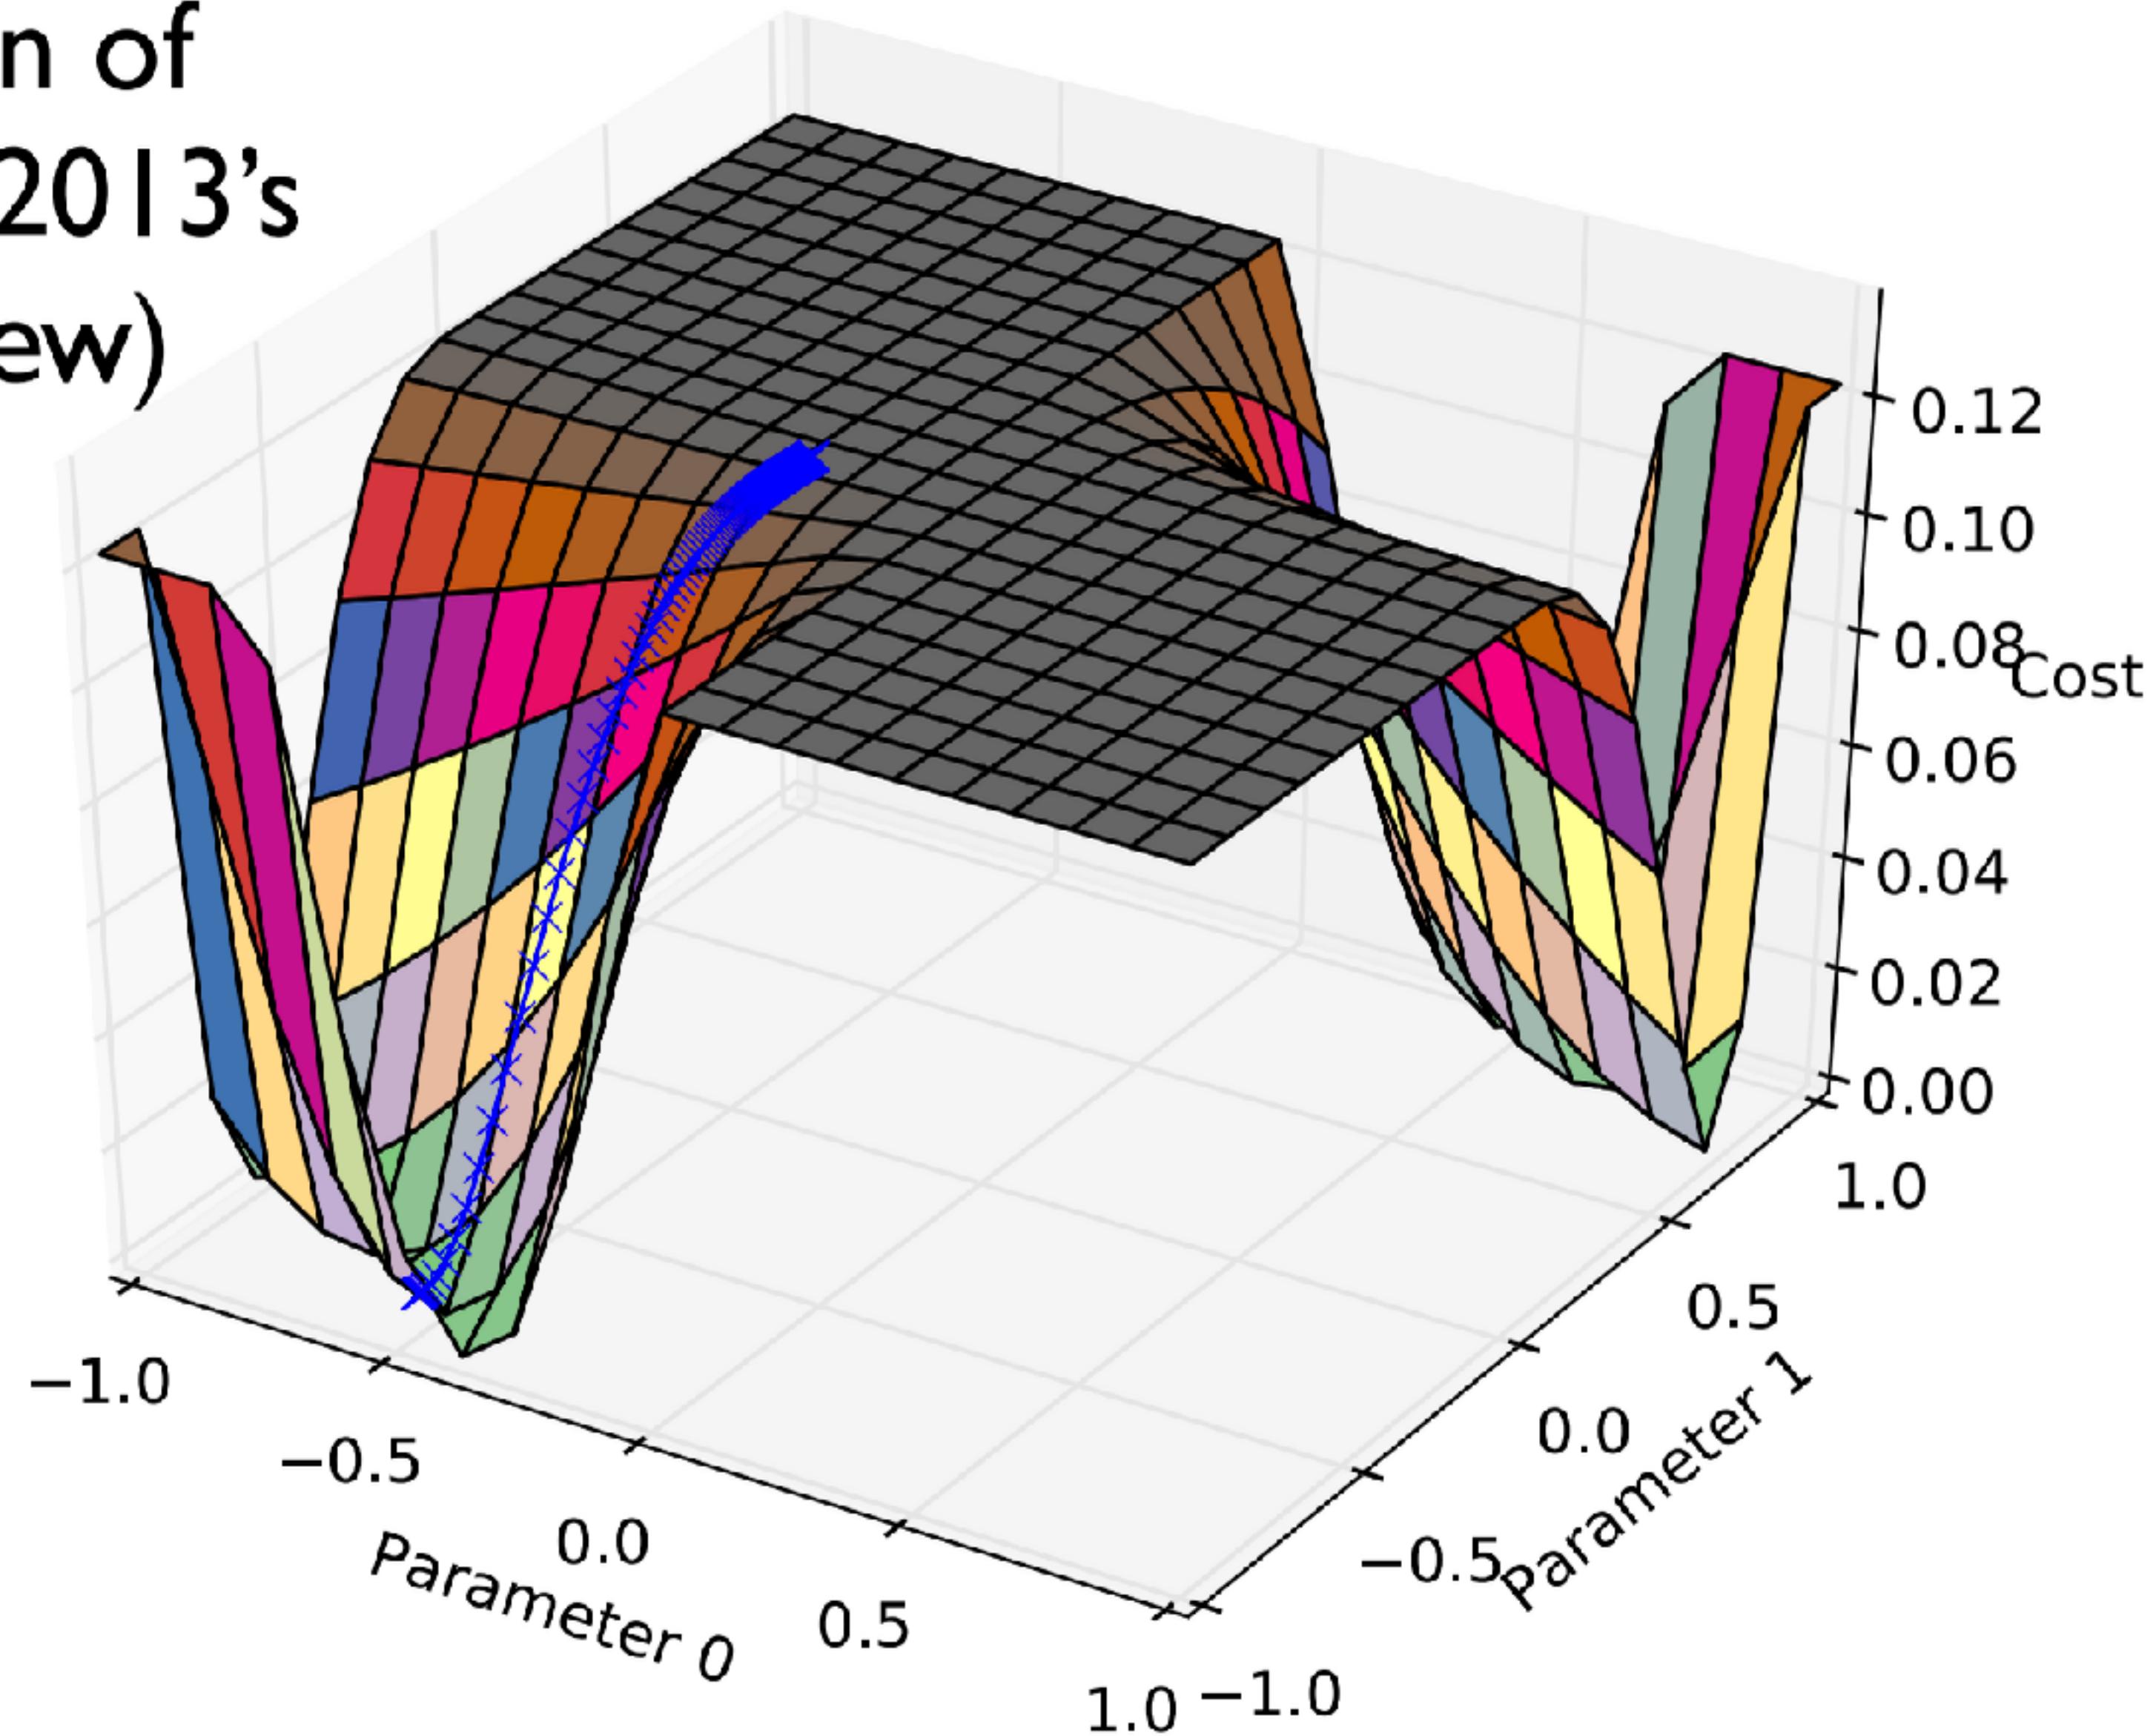

# Do neural nets have saddle points?

- Saxe et al, 2013:
- neural nets without non-linearities have many saddle points
- all the minima are global
- all the minima form a connected manifold

(Cartoon of  
Saxe et al 2013's  
worldview)

# Do neural nets have saddle points?

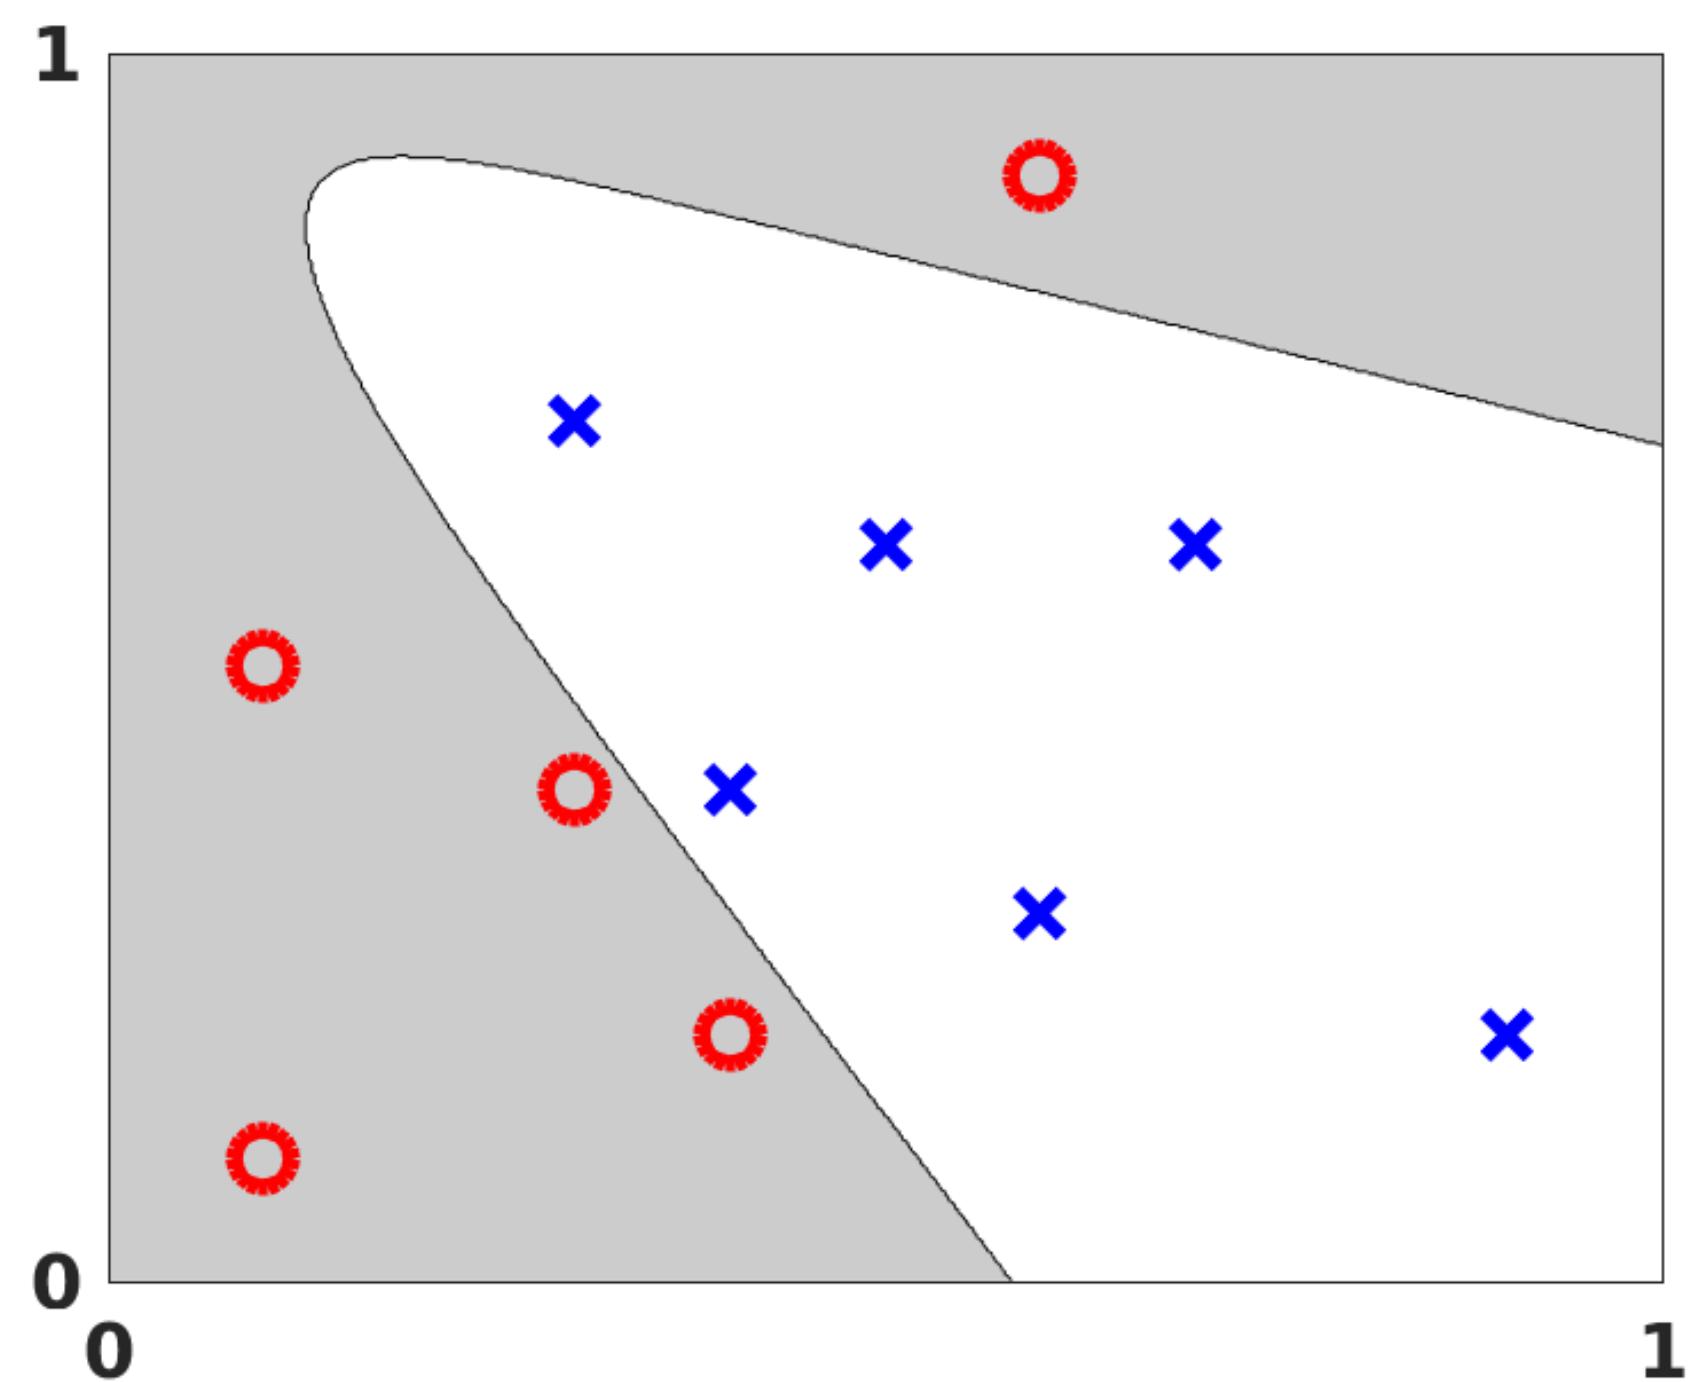

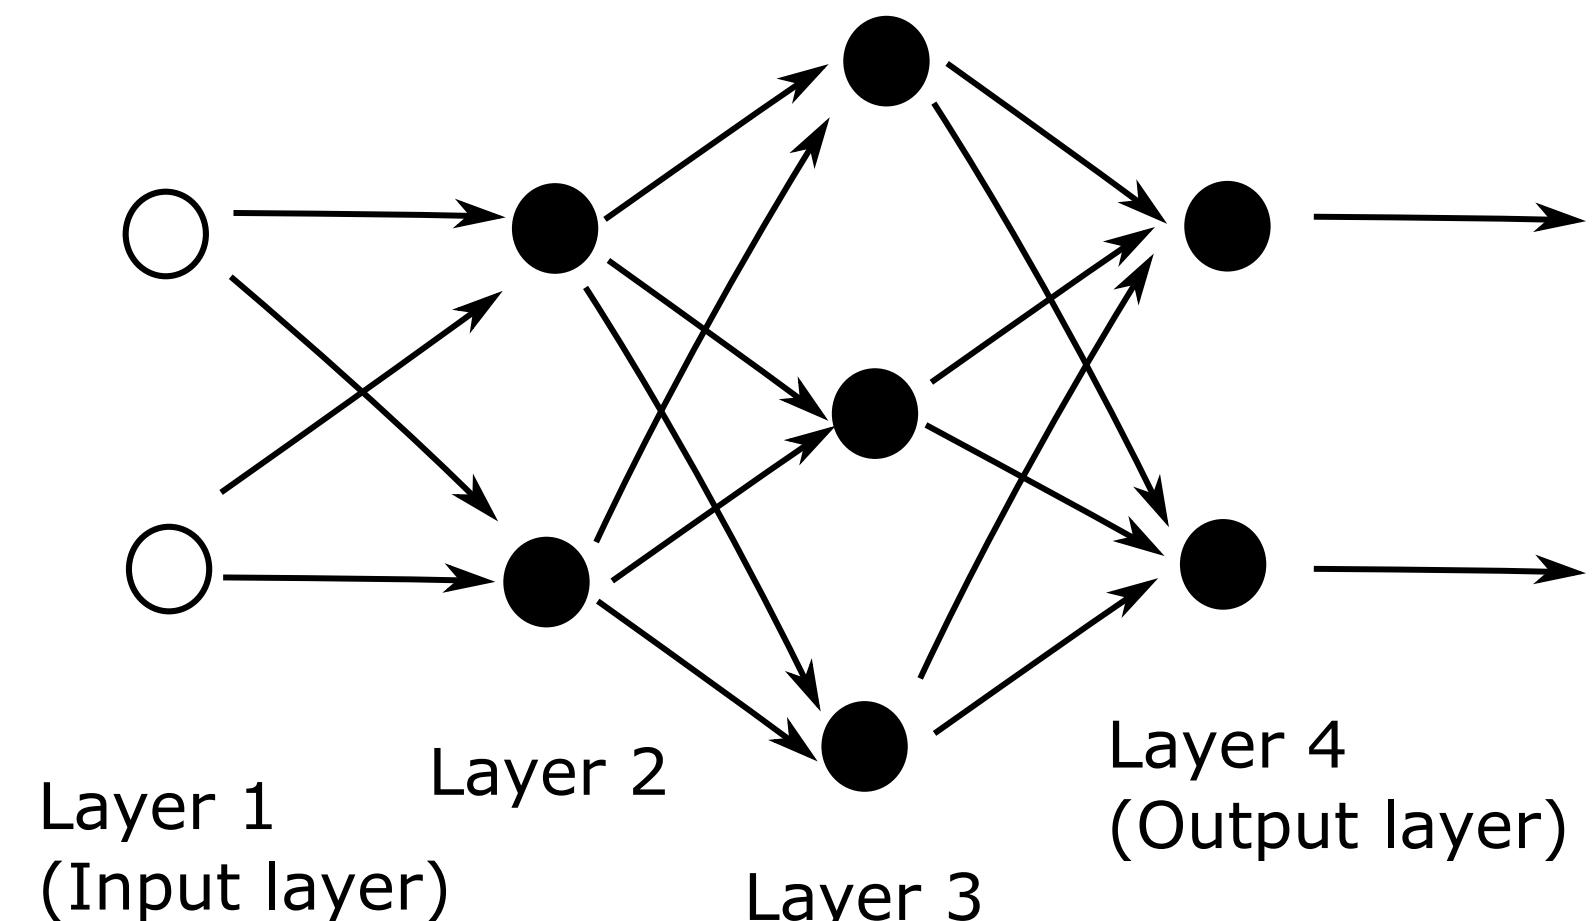

- Dauphin et al 2014: Experiments show neural nets do have as many saddle points as random matrix theory predicts
- Choromanska et al 2015: Theoretical argument for why this should happen
- Major implication: **most minima are good, and this is more true for big models.**
- Minor implication: the reason that *Newton's method* works poorly for neural nets is its attraction to the ubiquitous saddle points.

## Abstract

Gradient descent-based optimization methods underpin the parameter training of neural networks, and hence comprise a significant component in the impressive test results found in a number of applications. Introducing stochasticity is key to their success in practical problems, and there is some understanding of the role of stochastic gradient descent in this context. Momentum modifications of gradient descent such as Polyak's Heavy Ball method (HB) and Nesterov's method of accelerated gradients (NAG), are also widely adopted. In this work our focus is on understanding the role of momentum in the training of neural networks, concentrating on the common situation in which the momentum contribution is fixed at each step of the algorithm. To expose the ideas simply we work in the deterministic setting.

Our approach is to derive continuous time approximations of the discrete algorithms; these continuous time approximations provide insights into the mechanisms at play within the discrete algorithms. We prove three such approximations. Firstly we show that standard implementations of fixed momentum methods approximate a time-rescaled gradient descent flow, asymptotically as the learning rate shrinks to zero; this result does not distinguish momentum methods from pure gradient descent, in the limit of vanishing learning

# Adaptive gradient methods

---

**Algorithm 8.4** The AdaGrad algorithm

---

**Require:** Global learning rate  $\epsilon$

**Require:** Initial parameter  $\boldsymbol{\theta}$

**Require:** Small constant  $\delta$ , perhaps  $10^{-7}$ , for numerical stability

Initialize gradient accumulation variable  $\mathbf{r} = \mathbf{0}$

**while** stopping criterion not met **do**

    Sample a minibatch of  $m$  examples from the training set  $\{\mathbf{x}^{(1)}, \dots, \mathbf{x}^{(m)}\}$  with corresponding targets  $\mathbf{y}^{(i)}$ .

    Compute gradient:  $\mathbf{g} \leftarrow \frac{1}{m} \nabla_{\boldsymbol{\theta}} \sum_i L(f(\mathbf{x}^{(i)}; \boldsymbol{\theta}), \mathbf{y}^{(i)})$ .

    Accumulate squared gradient:  $\mathbf{r} \leftarrow \mathbf{r} + \mathbf{g} \odot \mathbf{g}$ .

    Compute update:  $\Delta \boldsymbol{\theta} \leftarrow -\frac{\epsilon}{\delta + \sqrt{\mathbf{r}}} \odot \mathbf{g}$ . (Division and square root applied element-wise)

    Apply update:  $\boldsymbol{\theta} \leftarrow \boldsymbol{\theta} + \Delta \boldsymbol{\theta}$ .

**end while**

---

# Adaptive gradient methods

---

**Algorithm 8.7** The Adam algorithm

---

**Require:** Step size  $\epsilon$  (Suggested default: 0.001)

**Require:** Exponential decay rates for moment estimates,  $\rho_1$  and  $\rho_2$  in  $[0, 1]$ .  
(Suggested defaults: 0.9 and 0.999 respectively)

**Require:** Small constant  $\delta$  used for numerical stabilization (Suggested default:  
 $10^{-8}$ )

**Require:** Initial parameters  $\boldsymbol{\theta}$

Initialize 1st and 2nd moment variables  $\mathbf{s} = \mathbf{0}$ ,  $\mathbf{r} = \mathbf{0}$

Initialize time step  $t = 0$

**while** stopping criterion not met **do**

    Sample a minibatch of  $m$  examples from the training set  $\{\mathbf{x}^{(1)}, \dots, \mathbf{x}^{(m)}\}$  with  
    corresponding targets  $\mathbf{y}^{(i)}$ .

    Compute gradient:  $\mathbf{g} \leftarrow \frac{1}{m} \nabla_{\boldsymbol{\theta}} \sum_i L(f(\mathbf{x}^{(i)}; \boldsymbol{\theta}), \mathbf{y}^{(i)})$

$t \leftarrow t + 1$

    Update biased first moment estimate:  $\hat{\mathbf{s}} \leftarrow \rho_1 \mathbf{s} + (1 - \rho_1) \mathbf{g}$

    Update biased second moment estimate:  $\hat{\mathbf{r}} \leftarrow \rho_2 \mathbf{r} + (1 - \rho_2) \mathbf{g} \odot \mathbf{g}$

    Correct bias in first moment:  $\hat{\mathbf{s}} \leftarrow \frac{\hat{\mathbf{s}}}{1 - \rho_1^t}$

    Correct bias in second moment:  $\hat{\mathbf{r}} \leftarrow \frac{\hat{\mathbf{r}}}{1 - \rho_2^t}$

    Compute update:  $\Delta\boldsymbol{\theta} = -\epsilon \frac{\hat{\mathbf{s}}}{\sqrt{\hat{\mathbf{r}}} + \delta}$  (operations applied element-wise)

    Apply update:  $\boldsymbol{\theta} \leftarrow \boldsymbol{\theta} + \Delta\boldsymbol{\theta}$

**end while**
